Cells and molecular biology

Cell biology: the characteristics of cells, e.g., their physiological properties, structure, organelles, interactions with the environment, life cycle, division and death. **Understanding cells is crucial in comprehending life itself.**

Molecular & cellular biology are interrelated,

Most of cell properties & functions described at the molecular level. Various branches of biology, including biotechnology, developmental biology, physiology, pathology, genetics, microbiology, etc.

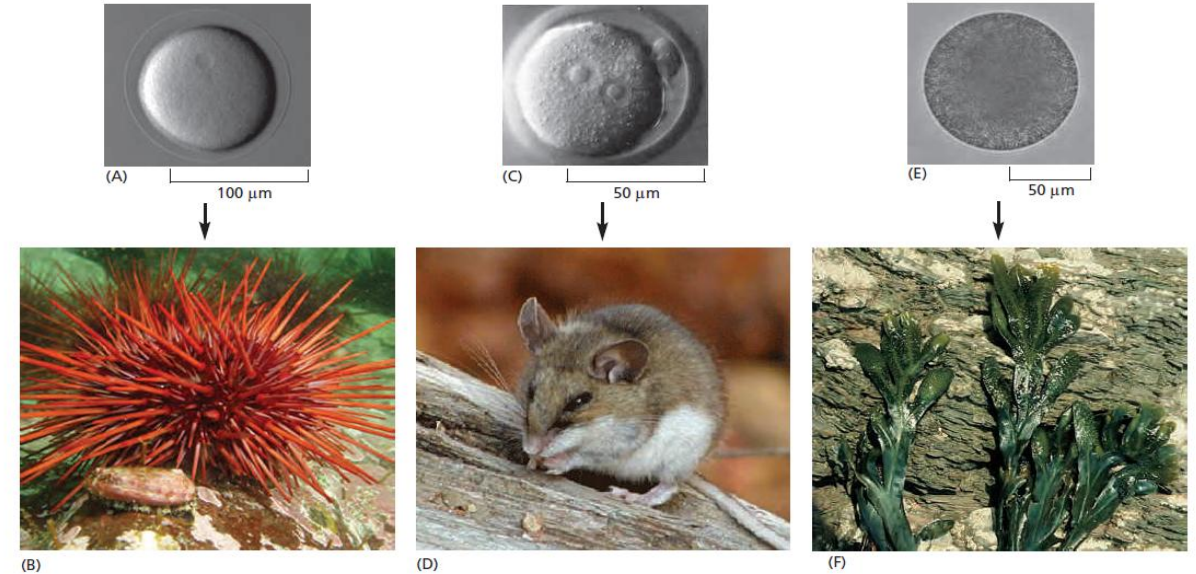

Molecular biology: the study of biology at the molecular level. Chiefly concerns itself with understanding & interactions between **DNA, RNA & proteins**, and learning **how these interactions are regulated.**

Life begins with cells

- ❖ The **individual cells** that form our bodies can grow, reproduce, process information, respond to stimuli, and carry out an amazing array of chemical reactions. **These ability define life.**

Chapter 1 Opener
Molecular Cell Biology, Sixth Edition
© 2008 W.H. Freeman and Company

- ❖ We & other multicellular microorganisms contain **billions or trillion of cells** organized into a **complex structure**.
- ❖ Even simple unicellular organisms exhibit all the hallmark properties of life, indicating that **the cell is the fundamental unit of life.**

All cells are prokaryotes and eukaryotes

Prokaryotic cells

“before nucleus”

(Bacteria, archaea)

Eukaryotic cells

“true nucleus”

(Plants, animals, fungi, protists)

Eukaryotic and Prokaryotic Cells: Similarities & Differences

Prokaryotes

- ❖ Oldest cell type
- ❖ Small & simple
- ❖ Lacks a defined nucleus
- ❖ Has a relatively simple
- ❖ Internal organization
- ❖ Lacks organelles
- ❖ **Unicellular**
- ❖ Circular DNA

Both

- ✓ DNA
- ✓ Ribosome
- ✓ Cytoplasm
- ✓ Plasma membrane

Eukaryotes

- ❖ Evolved from prokaryotes
- ❖ Larger and more complex
- ❖ Have nucleus
- ❖ Have membrane bound organelles
- ❖ Unicellular (yeast) or **multicellular** (animals)
- ❖ Linear DNA

Phylogeny of the three domains of life

- Presumed common progenitor of all extant organisms
- Presumed common progenitor of archaeobacteria and eukaryotes

All organisms from **simple bacteria** to **complex mammals** probably evolved from a common, **single celled progenitor**.

This **family tree** depicts **the evolutionary relations** among the three major lineages of organisms or domains namely **Archaea, Bacteria, Eukaryota**.

All animals, plants, fungi, and many unicellular organisms are **eukaryotes**.

Cells come in an amazing variety of shapes and sizes.

Eubacteria;
Lactococcus lactis,

A mass of
archaebacteria
(*Methanosarcina*)

Blood cells

Levels of organization of the human body

- The major levels of organization in the body, from the simplest to the most complex are: **atoms, molecules, organelles, cells, tissues, organs, organ systems, and**
- **Molecules** (Small molecules, precursors, intermediates, building blocks)
- **Macromolecules** (Biological molecules or Biomolecules): proteins, carbohydrates, lipids, nucleic acids
- **Cells** are basic structural and functional units of all living organisms

Molecules of a cell

Structural hierarchy in the molecular organization of cells

Essential elements for humans

ESSENTIAL ELEMENTS FOR HUMANS

There are 118 elements in the periodic table, but which of them are essential for human life? Here we zero in on the ones we can't live without and the roles they play.

THE ELEMENTAL COMPOSITION OF THE HUMAN BODY BY MASS

OXYGEN	CARBON	HYDROGEN	NITROGEN	OTHERS*
O 65%	C 18%	H 10%	N 3%	4%

* Includes Ca, P, K, S, Na, Cl, Mg, B, Cr, Co, Cu, F, I, Fe, Mn, Mo, Se, Si, Sn, V, and Zn.

BUILDING BLOCKS

H C N O P S

These elements (except phosphorus) are found in amino acids, the building blocks of proteins. With the exception of sulfur, they all also combine to make up DNA, our genetic code.

ENZYMES

Mg Mn Cu Zn Se Mo

Metal ions help many enzymes in the body function. Enzymes have many important roles in the body, including in respiration, digestion, metabolism, and the immune system.

NERVES AND CONTROL

Na Cl K Ca I

Sodium, potassium, and calcium ions play roles in transmitting nerve signals. Chloride ions regulate fluid in and out of cells. The body uses iodine to make hormones that regulate metabolism.

BONES AND TEETH

O P Ca Mn

Bones and teeth are mainly calcium phosphate. Calcium is essential for the growth of healthy teeth and bones. Without manganese, bones are spongier and break more easily.

BLOOD

C O Fe Co

Iron in hemoglobin carries oxygen from the lungs to the body's cells. And it carries carbon dioxide back to the lungs. Cobalt, found in vitamin B-12, is essential for making red blood cells.

RESPIRATION AND ENERGY

C N O P

Our cells use the oxygen we breathe for respiration. Respiration produces adenosine triphosphate (ATP, shown), a molecular energy source for our cells.

The human body is comprised of several major elements, including carbon, hydrogen, oxygen, nitrogen, calcium, phosphorus and potassium. Big 4 – 96%

[illegible]CCCCC/C=C\CCCC

- **Chain length**
- **Branching**
- **Double bonds**
- **Ring formations**

Chemistry of life: key concepts

Covalent and non-covalent interactions

Small molecules serve as building blocks for larger structures.

Chemical reactions

ATP the universal "currency" of chemical energy

Biomolecules - An overview

Carbohydrates

Proteins

Nucleic acids

Lipids

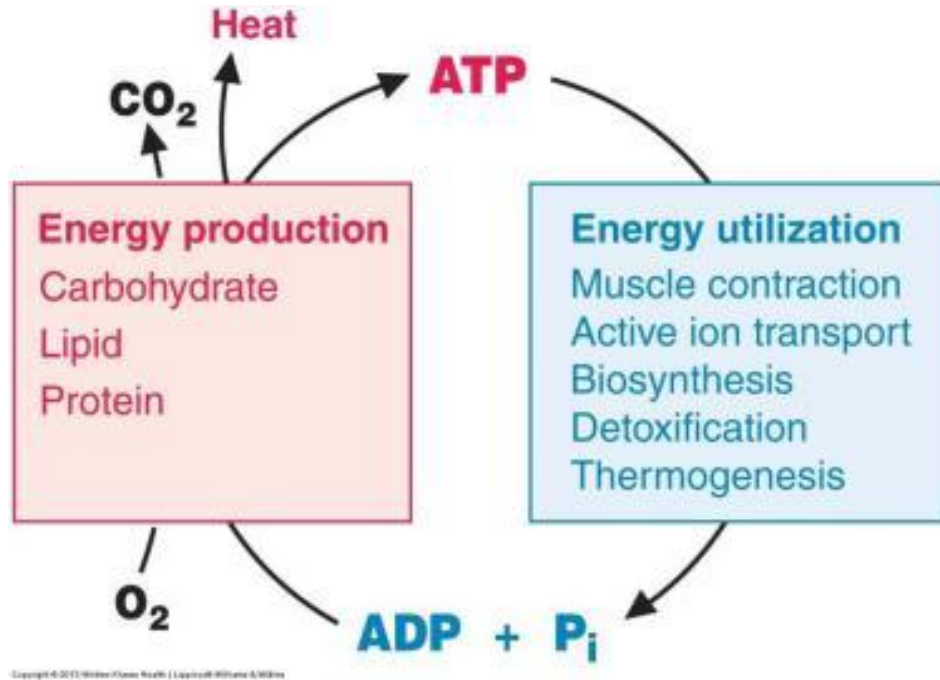

Organelles

Organelles are specialized structures that perform various jobs inside cells.

Nucleus	DNA Storage
Mitochondrion	Energy production
Golgi apparatus	Protein modification and export
Peroxisome	Lipid destruction; contains oxidative enzymes
Lysosome	Protein destruction
Cell membrane	Regulates the transport of materials entering and exiting the cell
Ribosome	Protein synthesis

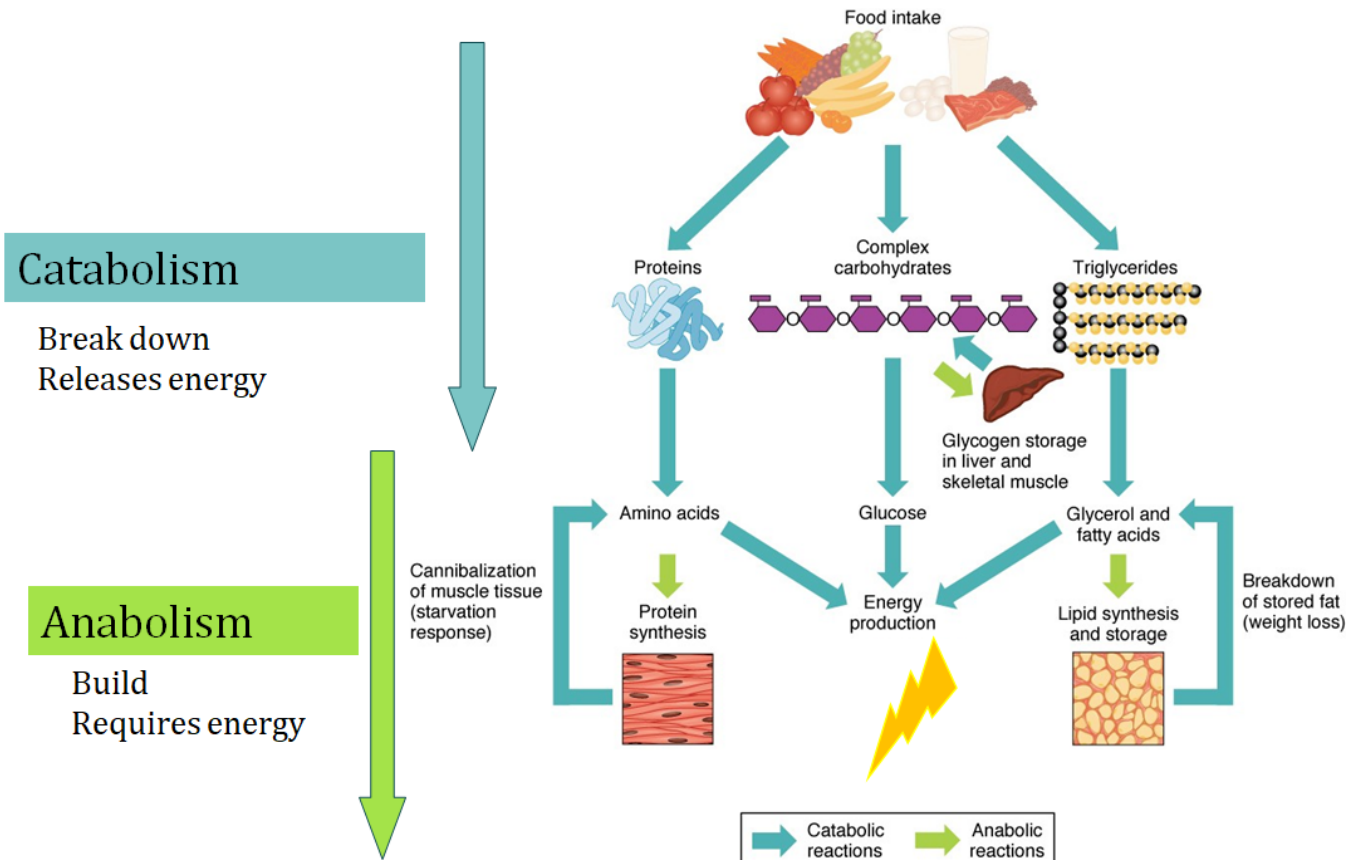

Bioenergetics

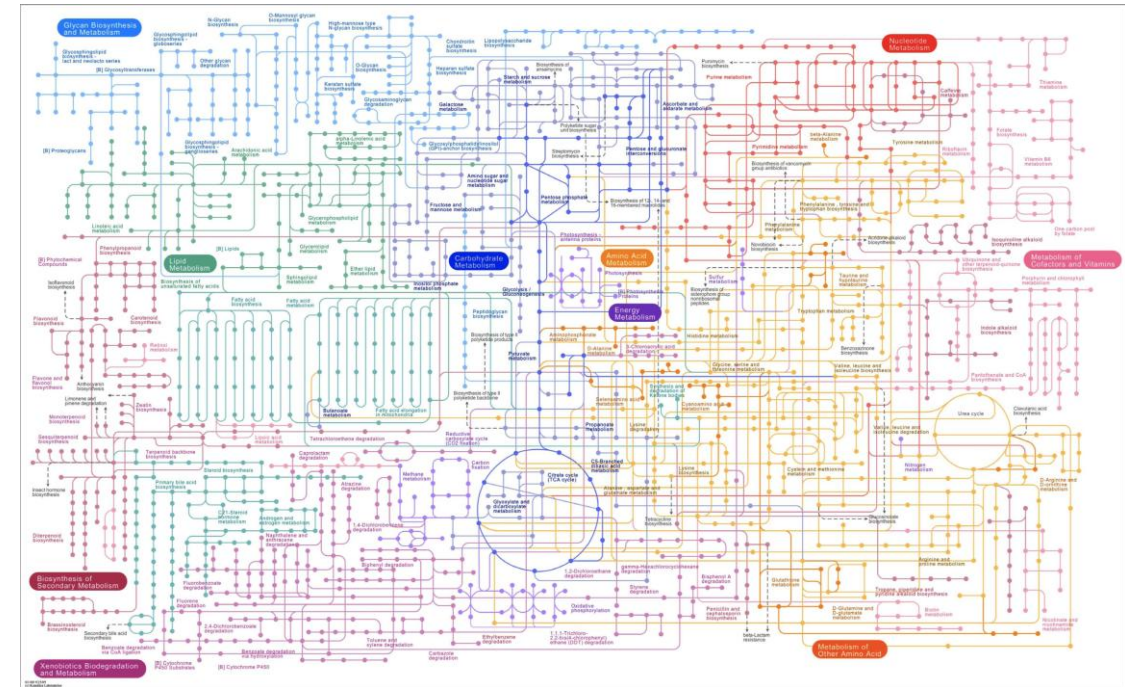

- ❖ To obtain energy for making ATP, cells break down food molecules.
- ❖ ATP is the most common molecule used by cells to capture and transfer energy.

Metabolism

“The sum of all the reactions in a cell or the body”

<https://www.mdpi.com/2072-6643/12/5/1265/htm>

Map of the human
metabolic pathway

Different cell types (e.g. RBC and brain) require different fuel molecules

Red blood cells rely on glucose for energy and convert glucose to lactate. The brain uses glucose & ketone bodies for energy.

How does the cell's organization of metabolism and regulation of signaling pathways, facilitated by membrane-bound compartments and receptors, contribute to cellular function?

The work of cells

Cell compartmentalization

If organelles could talk.

Beatrice the Biologist

Eukaryotes have a compartmentalized cell structure.

Plasma membranes separate the interior of all cells from the outside environment that prevents the free flow of molecules in and out.

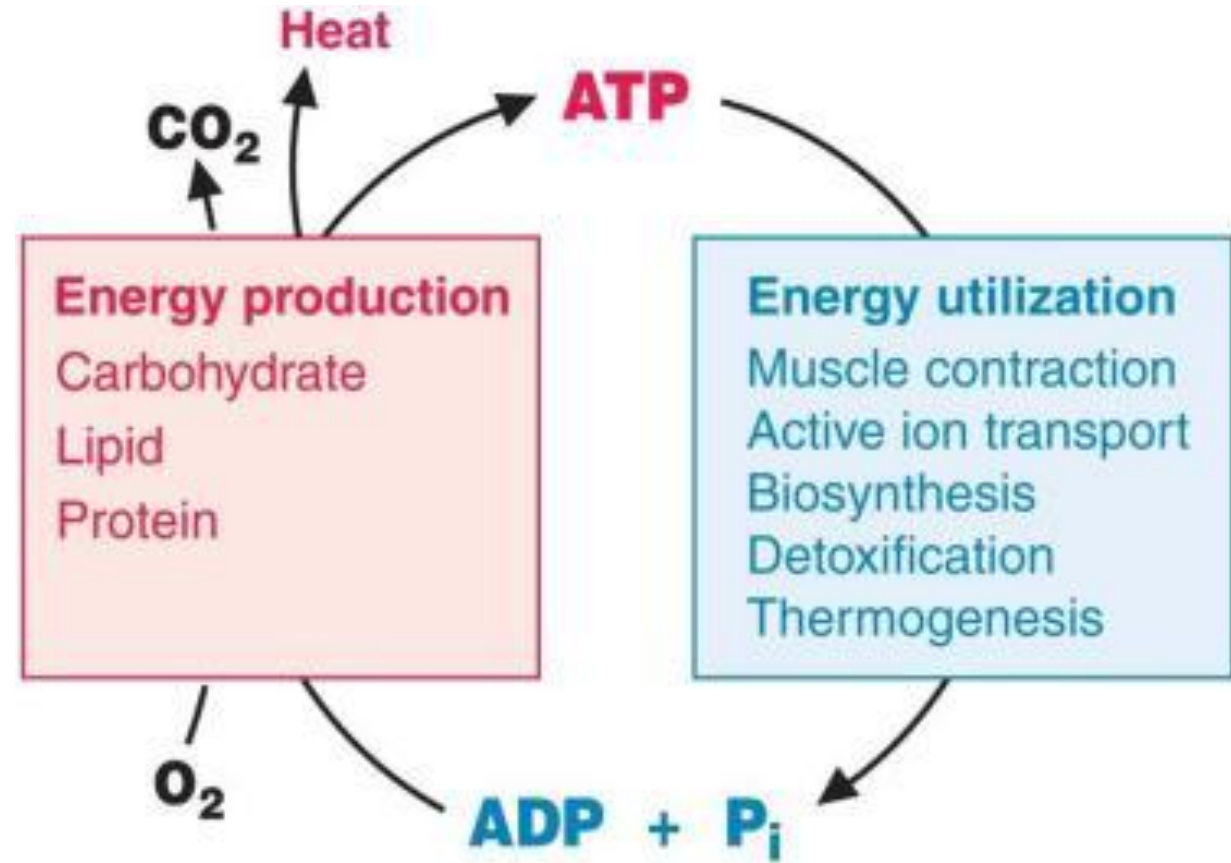

Membrane-bound organelles sub-divide into compartments allows for the creation of specific microenvironments within a cell.

Each organelle can have all the advantages it needs to perform to the best of its ability, e.g., specialized proteins/enzymes, a certain pH, each organelle has its own **assigned tasks in the overall work of the cell.**

The work of cells

Cells **build & degrade** numerous molecules & structures.

- ❖ Producing an enormous number of **complex molecules** from **simple building blocks**.
- ❖ Cells also need **to breakdown biomolecules** into small molecules.
- ❖ **ATP** is the most common molecule used by cells to capture and transfer energy.

Copyright © 2011 Wolters Kluwer Health | Lippincott Williams & Wilkins

The work of cells

- **Animal cells produce their own external environment and glues.** Extracellular cellular matrix such as collagen, cell adhesion molecules (CAMs) etc.
- **Cells change shape and move.** Cytoskeleton structure: network of fibers extending throughout cytoplasm. Cytoskeleton function: structural support, maintain cell shape, cell locomotion, transport of vesicles etc.

Intermediate filaments

Microtubules

Microfilaments

The three types of cytoskeletal filaments have characteristic distributions within cells.

The work of cells

Cells sense & send information.

The work of cells

- ❖ Cells regulate their gene expression to meet changing needs. Gene expression and regulation.
- ❖ Cells grow and divide.
- ❖ Cells die from aggravated assault or internal program (apoptosis).

Investigating cells & their parts

- ❖ Science is the way to understand nature
- ❖ Choice of experimental organism matters

Human?
Cell culture?
Animal?

(a)

Yeast (*Saccharomyces cerevisiae*)
Control of cell cycle and cell division
Protein secretion and membrane biogenesis
Function of the cytoskeleton
Cell differentiation
Aging
Gene regulation and chromosome structure

(b)

Alga (*Chlamydomonas reinhardtii*)
Structure and function of flagella
Chloroplasts and photosynthesis
Organelle movement
Phototaxis

(c)

Roundworm (*Caenorhabditis elegans*)
Development of the body plan
Cell lineage
Formation and function of the nervous system
Control of programmed cell death
Cell proliferation and cancer genes
Aging
Behavior
Gene regulation and chromosome structure

(d)

Fruit fly (*Drosophila melanogaster*)
Development of the body plan
Generation of differentiated cell lineages
Formation of the nervous system, heart, and musculature
Programmed cell death
Genetic control of behavior
Cancer genes and control of cell proliferation
Control of cell polarization
Effects of drugs, alcohol, pesticides

(e)

Planarian (*Schmidtea mediterranea*)
Stem cells
Turnover of adult tissues
Wound healing
Regeneration
Pharynx
Photoreceptors

(f)

Zebrafish (*Danio rerio*)
Development of vertebrate body tissues
Formation and function of brain and nervous system
Birth defects
Cancer

(g)

Mouse (*Mus musculus*), including cultured cells
Development of body tissues
Function of mammalian immune system
Formation and function of brain and nervous system
Models of cancers and other human diseases
Gene regulation and inheritance
Infectious disease
Behavior

(h)

Plant (*Arabidopsis thaliana*)
Development and patterning of tissues
Genetics of cell biology
Agricultural applications
Physiology
Gene regulation
Immunity
Infectious disease

Bacteria
Proteins involved in DNA, RNA, protein synthesis, metabolism
Gene regulation
Targets for new antibiotics
Cell cycle
Signaling

Viruses
Proteins involved in DNA, RNA, protein synthesis
Gene regulation
Cancer and control of cell proliferation
Transport of proteins and organelles inside cells
Infection and immunity
Possible gene therapy approaches

Each eukaryotic organism used in cell biology has advantages for certain types of studies.
